XML

Semistructured Data Extensible Markup Language Document Type Definitions

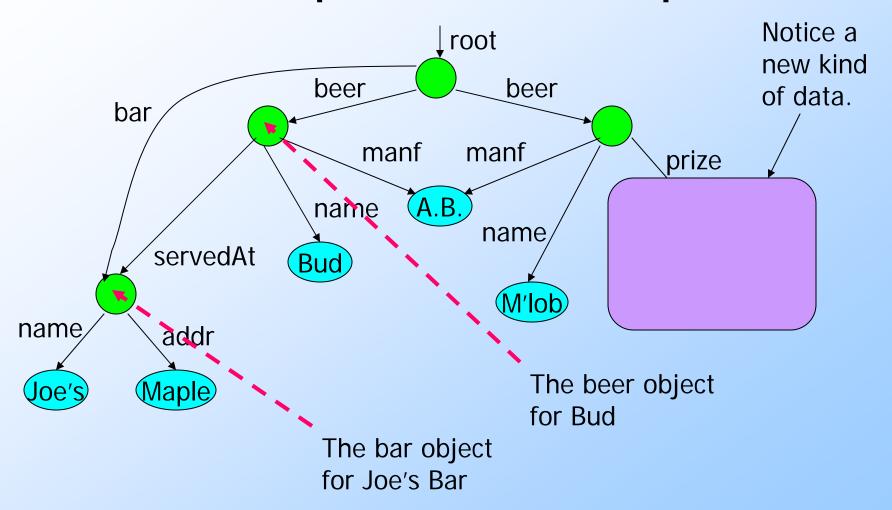

Semistructured Data

- Another data model, based on trees.
- Motivation: flexible representation of data.
 - Often, data comes from multiple sources with differences in notation, meaning, etc.
- Motivation: sharing of documents among systems and databases.

Graphs of Semistructured Data

- Nodes = objects.
- Labels on arcs (attributes, relationships).
- Atomic values at leaf nodes (nodes with no arcs out).
- Flexibility: no restriction on:
 - Labels out of a node.
 - Number of successors with a given label.

Example: Data Graph

XML

- ◆XML = Extensible Markup Language.
- While HTML uses tags for formatting (e.g., "italic"), XML uses tags for semantics (e.g., "this is an address").
- Key idea: create tag sets for a domain (e.g., genomics), and translate all data into properly tagged XML documents.

Well-Formed and Valid XML

- Well-Formed XML allows you to invent your own tags.
 - Similar to labels in semistructured data.
- ◆ Valid XML involves a DTD (Document Type Definition), a grammar for tags.

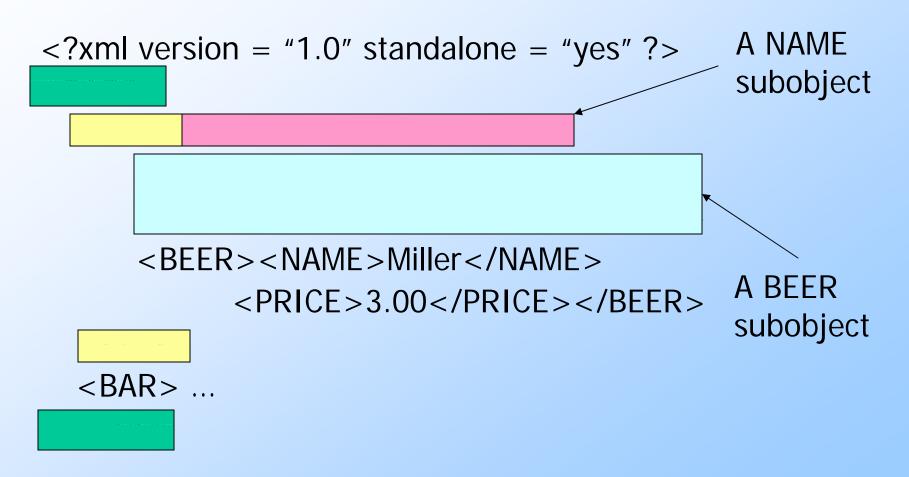

Well-Formed XML

- Start the document with a declaration, surrounded by <?xml ... ?> .
- Normal declaration is:
- <?xml version = "1.0"
 standalone = "yes" ?>
 - "Standalone" = "no DTD provided."
- Balance of document is a root tag surrounding nested tags.

Tags

- Tags, as in HTML, are normally matched pairs, as <FOO> ... </FOO> .
- Tags may be nested arbitrarily.
- XML tags are case sensitive.

Example: Well-Formed XML

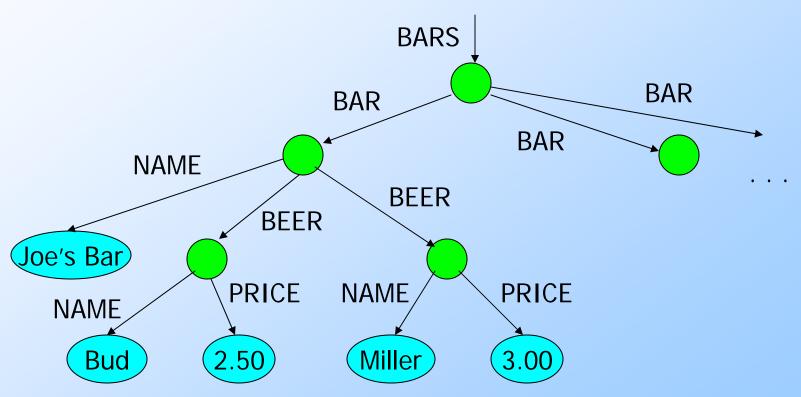

XML and Semistructured Data

- Well-Formed XML with nested tags is exactly the same idea as trees of semistructured data.
- We shall see that XML also enables nontree structures, as does the semistructured data model.

Example

◆The <BARS> XML document is:

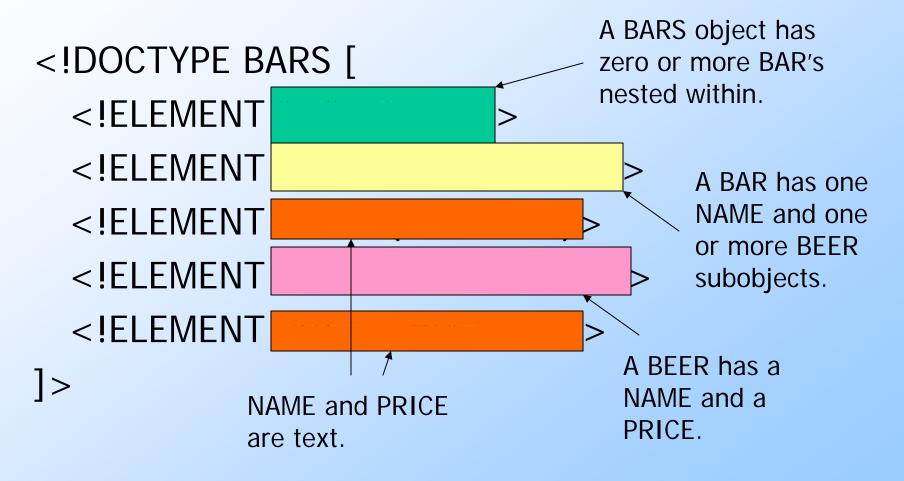

DTD Structure

```
<!DOCTYPE <root tag> [
    <!ELEMENT <name>(<components>)>
    . . . more elements . . .
]>
```

DTD Elements

- The description of an element consists of its name (tag), and a parenthesized description of any nested tags.
 - Includes order of subtags and their multiplicity.
- Leaves (text elements) have #PCDATA (Parsed Character DATA) in place of nested tags.

Example: DTD

Element Descriptions

- Subtags must appear in order shown.
- A tag may be followed by a symbol to indicate its multiplicity.
 - * = zero or more.
 - + = one or more.
 - ? = zero or one.
- Symbol | can connect alternative sequences of tags.

Example: Element Description

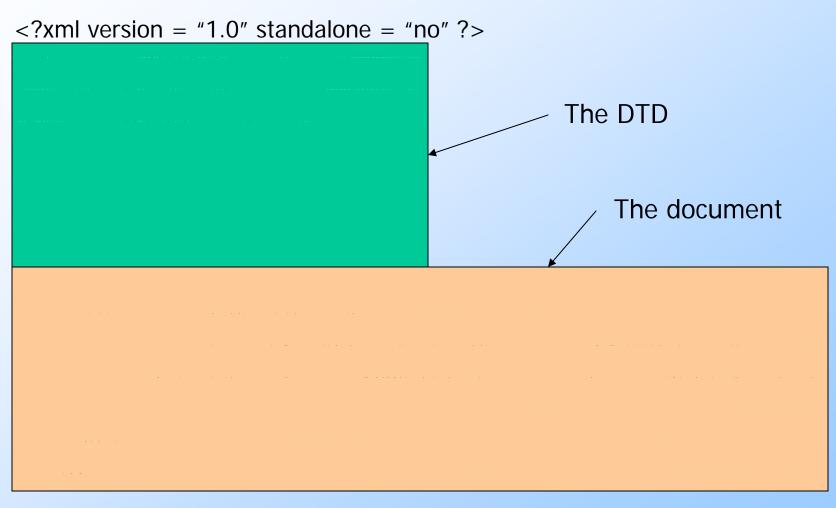

A name is an optional title (e.g., "Prof."), a first name, and a last name, in that order, or it is an IP address:

```
<!ELEMENT NAME (
   (TITLE?, FIRST, LAST) | IPADDR
)>
```

Use of DTD's

- 1. Set standalone = "no".
- 2. Either:
 - a) Include the DTD as a preamble of the XML document, or
 - b) Follow DOCTYPE and the <root tag> by SYSTEM and a path to the file where the DTD can be found.

Example (a)

Example (b)

Assume the BARS DTD is in file bar.dtd.

```
<?xml version = "1.0" standalone = "no" ?>
```

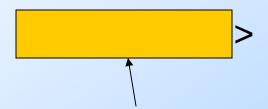

Attributes

- Opening tags in XML can have attributes.
- ◆In a DTD,
- <!ATTLIST E...>

declares an attribute for element *E*, along with its datatype.

Example: Attributes

- Bars can have an attribute kind, a character string describing the bar.
- <!ELEMENT BAR (NAME BEER*)>
 - <!ATTLIST BAR kind

Attribute is optional opposite: #REQUIRED

Character string type; no tags

Example: Attribute Use

In a document that allows BAR tags, we might see:

</BAR>

ID's and IDREF's

- Attributes can be pointers from one object to another.
 - Compare to HTML's NAME = "foo" and HREF = "#foo".
- Allows the structure of an XML document to be a general graph, rather than just a tree.

Creating ID's

- Give an element E an attribute A of type ID.
- When using tag < E > in an XML document, give its attribute A a unique value.
- **Example:**

$$A = "xyz">$$

Creating IDREF's

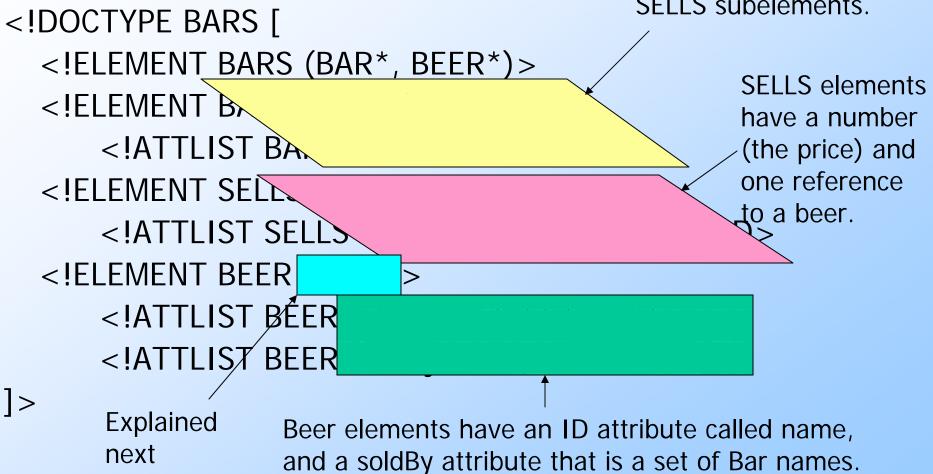

- ◆To allow objects of type F to refer to another object with an ID attribute, give F an attribute of type IDREF.
- ◆Or, let the attribute have type IDREFS, so the F –object can refer to any number of other objects.

Example: ID's and IDREF's

- Let's redesign our BARS DTD to include both BAR and BEER subelements.
- Both bars and beers will have ID attributes called name.
- ◆Bars have SELLS subobjects, consisting of a number (the price of one beer) and an IDREF theBeer leading to that beer.
- ◆Beers have attribute soldBy, which is an IDREFS leading to all the bars that sell it.

The DTD

Bar elements have name as an ID attribute and have one or more SELLS subelements.

Example Document

```
<BARS>
  <BAR name = "JoesBar">
     <SELLS theBeer = "Bud">2.50</SELLS>
     <SELLS theBeer = "Miller">3.00</SELLS>
  </BAR> ...
  <BEER name = "Bud" soldBy = "JoesBar
     SuesBar ..."/> ...
  </BARS>
```

Empty Elements

- We can do all the work of an element in its attributes.
 - Like BEER in previous example.
- Another example: SELLS elements could have attribute price rather than a value that is a price.

Example: Empty Element

- In the DTD, declare:
- <!ELEMENT SELLS EMPTY>
 - <!ATTLIST SELLS theBeer IDREF #REQUIRED>
 - <!ATTLIST SELLS price CDATA #REQUIRED>
- Example use:
- <SELLS theBeer = "Bud" price = "2.50]

Note exception to "matching tags" rule
